Reducing US Food Surplus by 33 Percent Through Precision Policy

A Data-Driven Analysis of Five ReFED Datasets | 50 States, 5 Sectors, 285 Food Categories (2010 to 2024)

Akshara Tarikere and Harshith Kandaru | GW Data Science Association Hackathon 2026

Executive Summary

The United States generates approximately 67.8 million tons of food surplus every year, representing 297 billion dollars in economic value lost, 201 million metric tons of CO2e emitted, and 110 billion meals discarded. At the same time, 47 million Americans face food insecurity. This brief presents the Smart Food Waste Reduction Act, a five-pillar federal policy framework developed through analysis of five ReFED Food Waste Monitor datasets covering more than 294,000 state-level records from 2010 to 2024. The framework is supported by a 23-page interactive platform deployed on Hugging Face Spaces and is projected to reduce annual US food surplus by 33 percent, recover more than 66 billion dollars in economic value, and generate enough meals to feed 11 billion people annually.

Five Findings That Contradict the Conventional Narrative

Analysis using K-Means clustering, Pearson correlation, linear regression forecasting, anomaly detection, and composite scoring reveals five findings that fundamentally challenge how policymakers have historically approached food waste.

1. Households, Not Restaurants, Are the Largest Waste Sector

The Residential sector generates over 270 million tons annually, surpassing Foodservice. Most food waste legislation targets commercial operators. The data demonstrates that households are the primary source of surplus by volume, and any strategy that ignores this will structurally underperform.

2. Foodservice Sends 74.9 Percent of Its Surplus Directly to Landfill

Foodservice has the worst diversion rate of any sector. Retail donates 30.4 percent of its surplus by comparison. This gap is regulatory rather than operational. Foodservice faces no federal obligation to divert organic waste, and no such obligation has been imposed at the national level.

3. Prepared Foods Discards 97.7 Percent of Its Supply

Prepared Foods carries a waste rate of 97.7 percent of total supply, the highest of any food type. This reflects structural overproduction in the complete absence of demand forecasting requirements, not consumer behavior.

4. Processing Waste Exceeds Field Abandonment as the Primary Root Cause

Trimmings and Byproducts is the largest cause group at over 200 billion tons, ahead of Fields Never Harvested. Waste is embedded in food processing before products reach retail shelves. This stream has never been subject to a federal reporting requirement or diversion mandate.

5. California Accounts for 17.6 Percent of National Surplus

California generates 12.44 million tons of food surplus per year. A targeted federal pilot in one state can move the national baseline measurably within two to three years and provide a replicable model for the remaining 49 states.

The Waste and Hunger Nexus

Pearson correlation analysis merging ReFED state-level surplus data with USDA ERS 2022 Food Security Survey rates and US Census 2022 population figures identifies a documented relationship between food waste per capita and food insecurity across all 50 states. States classified as critical, those with both above-median food waste per capita and above-median food insecurity rates, represent the highest-priority intervention targets. Analysis shows that redirecting 50 percent of surplus in critical states alone could feed 277 million people year-round without producing a single additional pound of food. The constraint is not the availability of food. It is cold-chain infrastructure, legal incentives, and real-time logistics.

Proposed Legislation: The Smart Food Waste Reduction Act

Five pillars sequenced by a composite scoring model weighting impact scale at 35 percent, political feasibility at 30 percent, speed at 20 percent, and ROI at 15 percent. All five operate within existing legal frameworks, require no new federal agencies, and together reduce annual US food surplus by approximately 33 percent.

Policy Pillar	Reduction	Timeline	Feasibility
Pillar 1: Residential Smart Date Labels. Unified federal use-by and best-by standard eliminates consumer confusion. FDA has existing statutory authority. No new infrastructure required.	~5.4M t/yr	1–2 yrs	**High**
Pillar 2: Foodservice Landfill Diversion Mandate. Operators above threshold must divert surplus via donation, composting, or anaerobic digestion. Modeled on Massachusetts 2014 Commercial Organics Ban.	~6.8M t/yr	1–3 yrs	**High**
Pillar 3: Prepared Foods Demand Intelligence Initiative. Federal grants for AI demand forecasting in the highest-waste food type. Mandatory annual waste rate reporting above production thresholds.	~3.4M t/yr	3–5 yrs	**Medium**
Pillar 4: Processing Byproduct Valorization Program. Tax credits for redirecting trimmings and byproducts to animal feed, biogas, or secondary products. Federal Byproduct Exchange and EPA report above 1,000 tons per year.	~5.4M t/yr	3–7 yrs	**Medium**
Pillar 5: California Federal Innovation Pilot Zone. Designates California as a Federal Innovation Zone combining all three policy layers. 17.6 percent of national surplus. Assessed at 24 months for national replication.	~1.4M t/yr	1–2 yrs	**High**

Projected Combined Impact

Full implementation of the five pillars reduces United States food surplus by approximately 33 percent within a decade. The combined federal investment of two to four billion dollars over five years generates a three-to-eight times return through food value recovery, carbon credits at 65 dollars per metric ton CO2e avoided, and water conservation value.

Metric	Projected Outcome	Significance
Total Surplus Reduced	22.4 million tons / year	33% of current US food surplus
Economic Value Recovered	$66 billion / year	3x to 8x per federal dollar invested
Meals Recovered	33 billion meals / year	Feeds 11 billion people annually
GHG Emissions Avoided	~4.2 million MTCO2e / year	Upstream and downstream combined
Federal Investment Required	$2–4 billion over 5 years	No new federal agencies required

Priority Recommendation: If Congress Can Pass One Law

The platform's composite scoring model ranked the Unified Federal Date Label Standard first among seven interventions, score 0.84 out of 1.00. More than 37 states use inconsistent label formats, causing consumers to discard billions of pounds of safe food. A single FDA rulemaking action prevents approximately 2.4 million tons from being discarded annually by households, recovering 3.6 billion meals and 1.4 billion dollars in value at a cost of roughly 50 million dollars. No new infrastructure is required, no industry opposition exists, and implementation takes 12 to 18 months.

Conclusion

The five-pillar Smart Food Waste Reduction Act reduces United States food surplus by one third within a decade. Every figure derives directly from the ReFED datasets. The cost of inaction is 297 billion dollars in wasted economic value, 110 billion meals discarded while 47 million Americans go hungry, and 201 million metric tons of avoidable emissions. The food exists. The hunger exists. The gap is a policy choice.

Primary data: ReFED Food Waste Monitor 2010–2024, five datasets, 294,000+ state-level records. **Supplementary:** USDA ERS Food Security Survey 2022; US Census Bureau 2022. **Methods:** K-Means clustering, PCA (78% variance), Pearson correlation, linear regression, anomaly detection at 1.5 SD, composite ROI model.
